Additional Information:
 Worldwide: 1990 to 2020

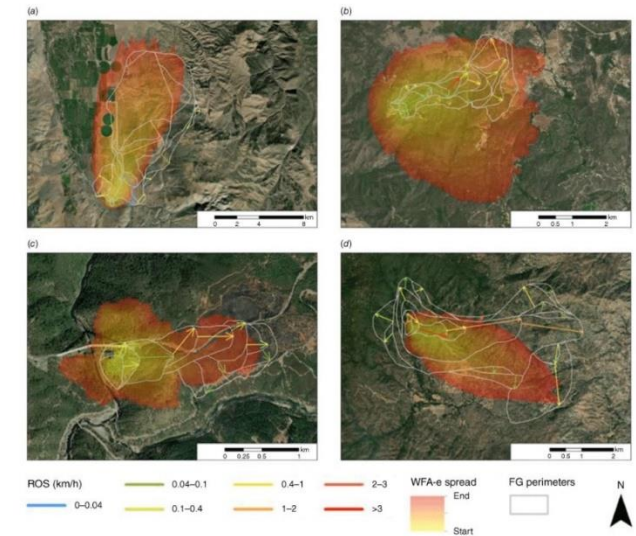

Wildfire Simulation

- ◆ Effective method for comprehending how fire spreads and evolves under different circumstances.
- ◆ Used by fire management agencies and decision-makers to analyze real-time fire behavior to:
 - develop effective suppression strategies.
 - evaluate the effectiveness of suppression efforts.
 - whether to evacuate a certain region or not.
 - wildfire prevention efforts such as controlled fuel management.

But...

The Accuracy of models depends on:

- Their limitations,
- assumptions,
- accuracy of input data

Simulation Accuracy

- ◆ ROS accuracy of five fuel-type specific fire spread models in Australia over 49 case studies (Cruz et al., 2018):
 - MAPE of 42% up to 124%
- ◆ ROS accuracy of the Rothermel model for 4 types over 29 case studies:
 - MAPE of 49% up to 76%
- ◆ Cardil et al., (2023) assessed the performance of operational fire spread models in California over 1853 fires:
 - MAPE of 26% up to 67%

Gaps & Challenges

- ◆ Accumulation of Errors
- ◆ Rate of Spread adjustment:
 - ◇ Rothermel and Rinehart (1983) and then by Finney (1998)
 - ◇ match the simulated ROS with the actual fire.
 - ◇ Evaluating manually, search for the optimal adjustments iteratively.
 - ◇ **However, manual work, error-prone, time-intensive**
 - ◇ **Require control points where the fire arrival time is known.**

Earth Observations

- ◆ Offer an invaluable resource to remotely monitor and characterize wildfire temporal and spatial evolution.
- ◆ Evaluate the discrepancies between fire simulations and actual fire spread cost-effectively.
- ◆ widely accessible and reliable resource.
- ◆ global coverage.
- ◆ readily and freely available through various online platforms.
- ◆ providing both historical records and near-real-time information.

Method

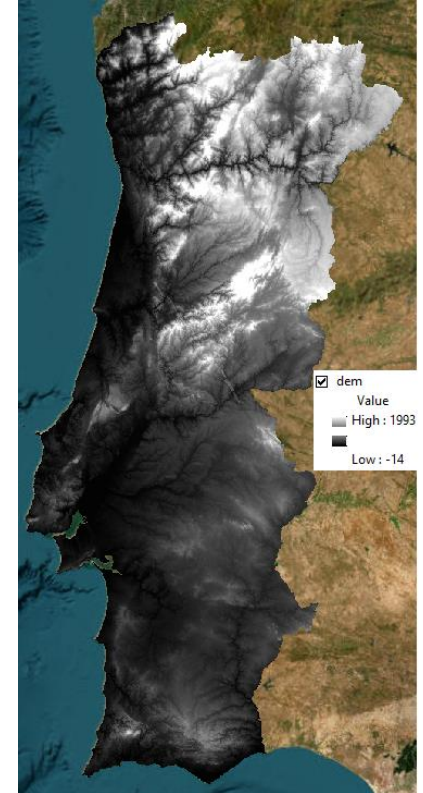

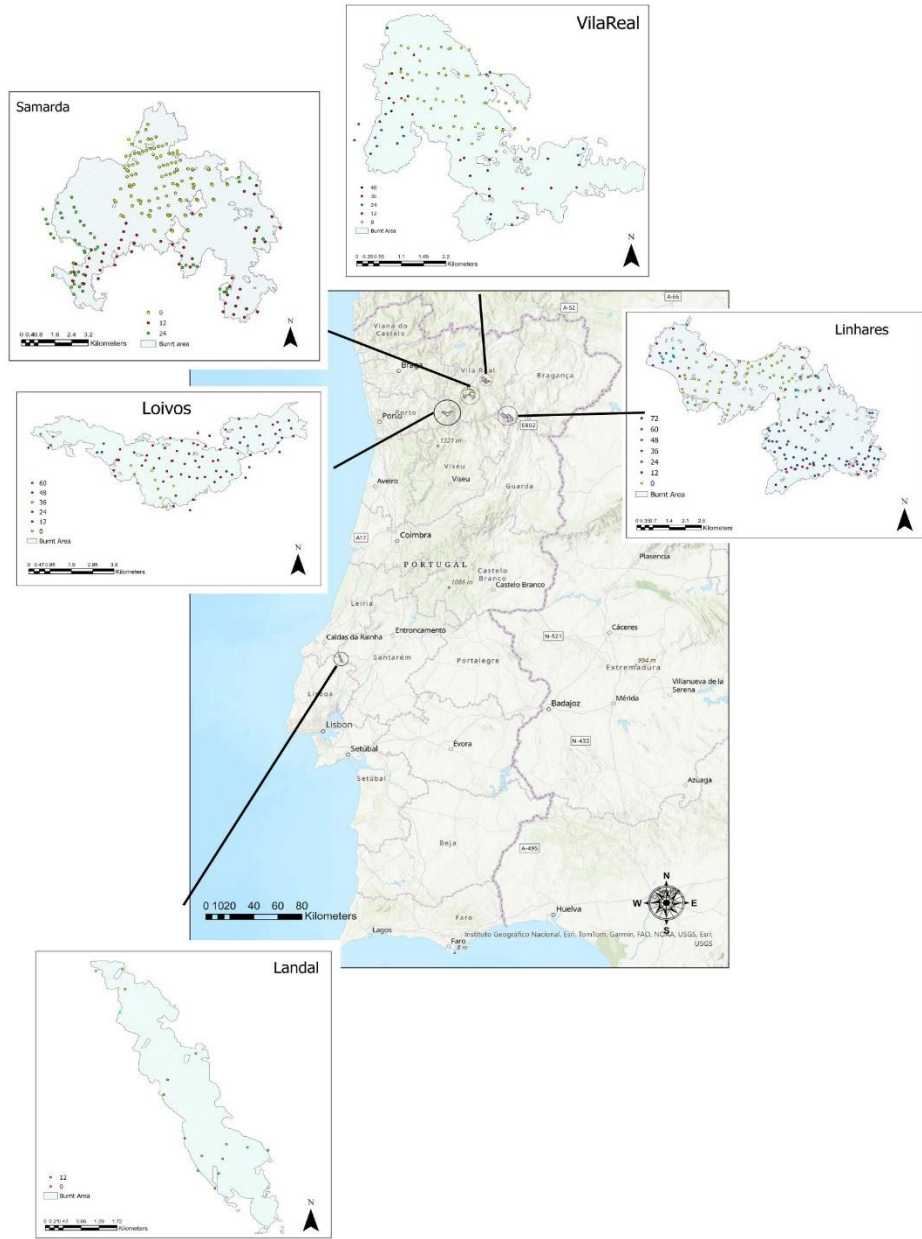

- ◆ Divide the total fire period into specific segments.
- ◆ Use an automatic algorithm for ROS adjustment.
- ◆ Use satellite active fire data for control points.
- ◆ Reinitialize the simulation each 12 hours aligned with satellite data.
- ◆ Adjust ROS of each segment and apply to the next interval.

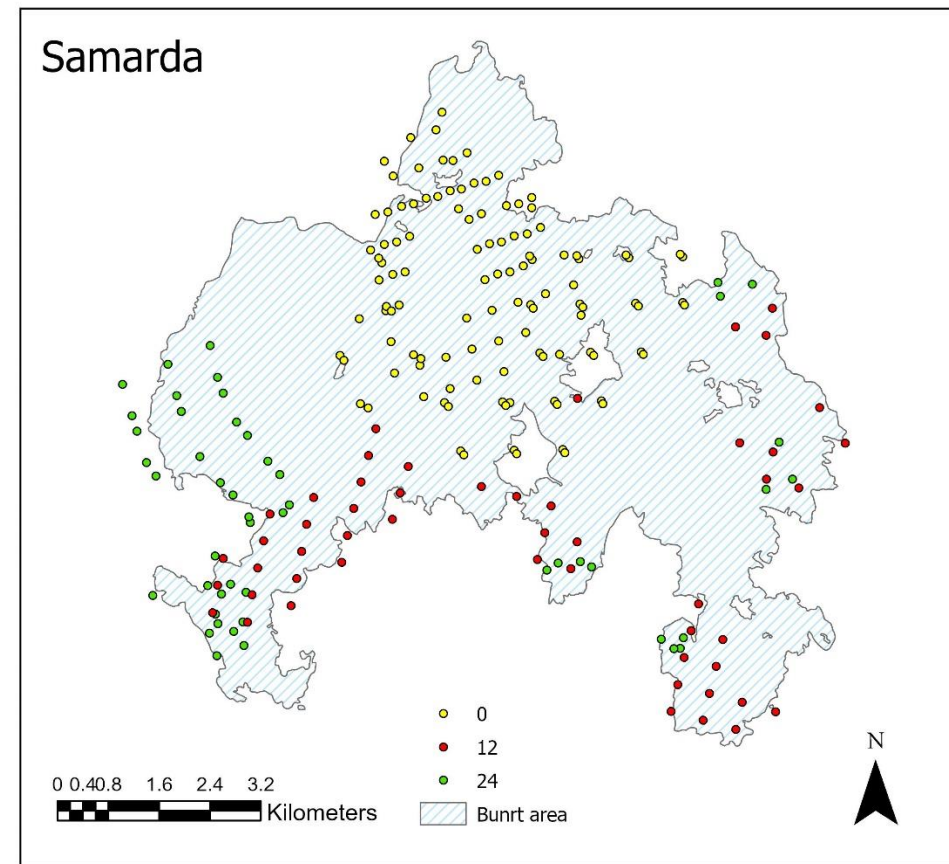

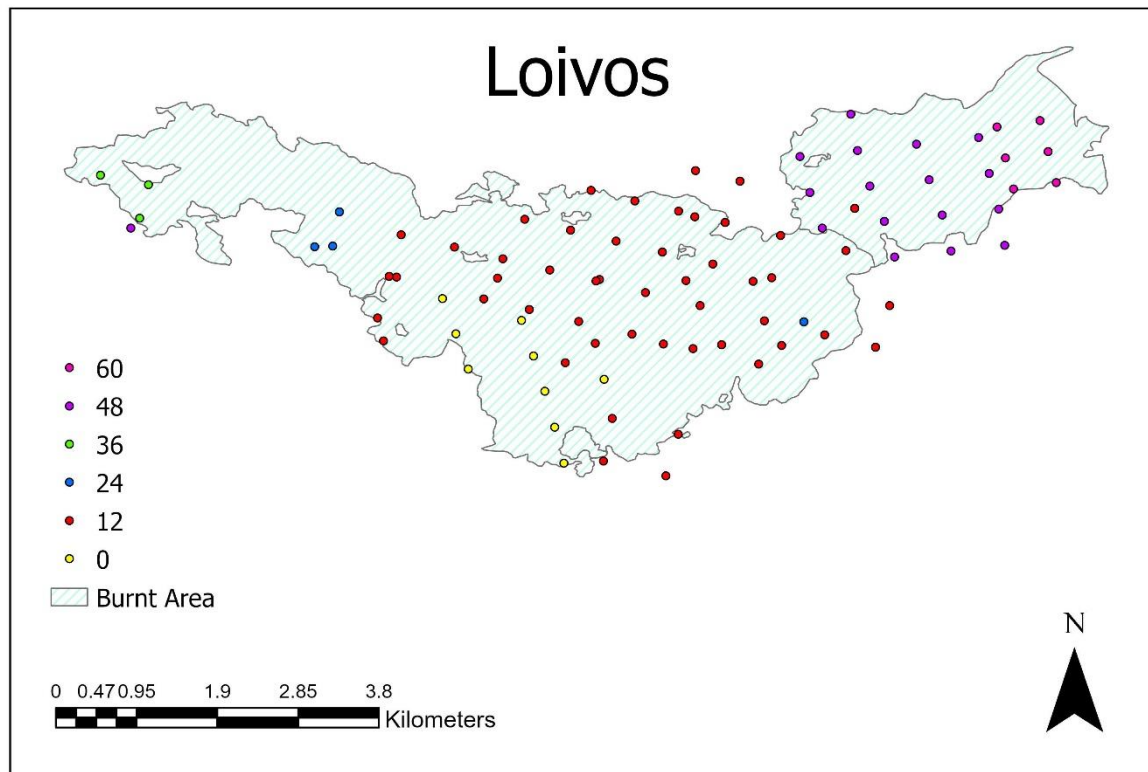

Wildfire Simulation

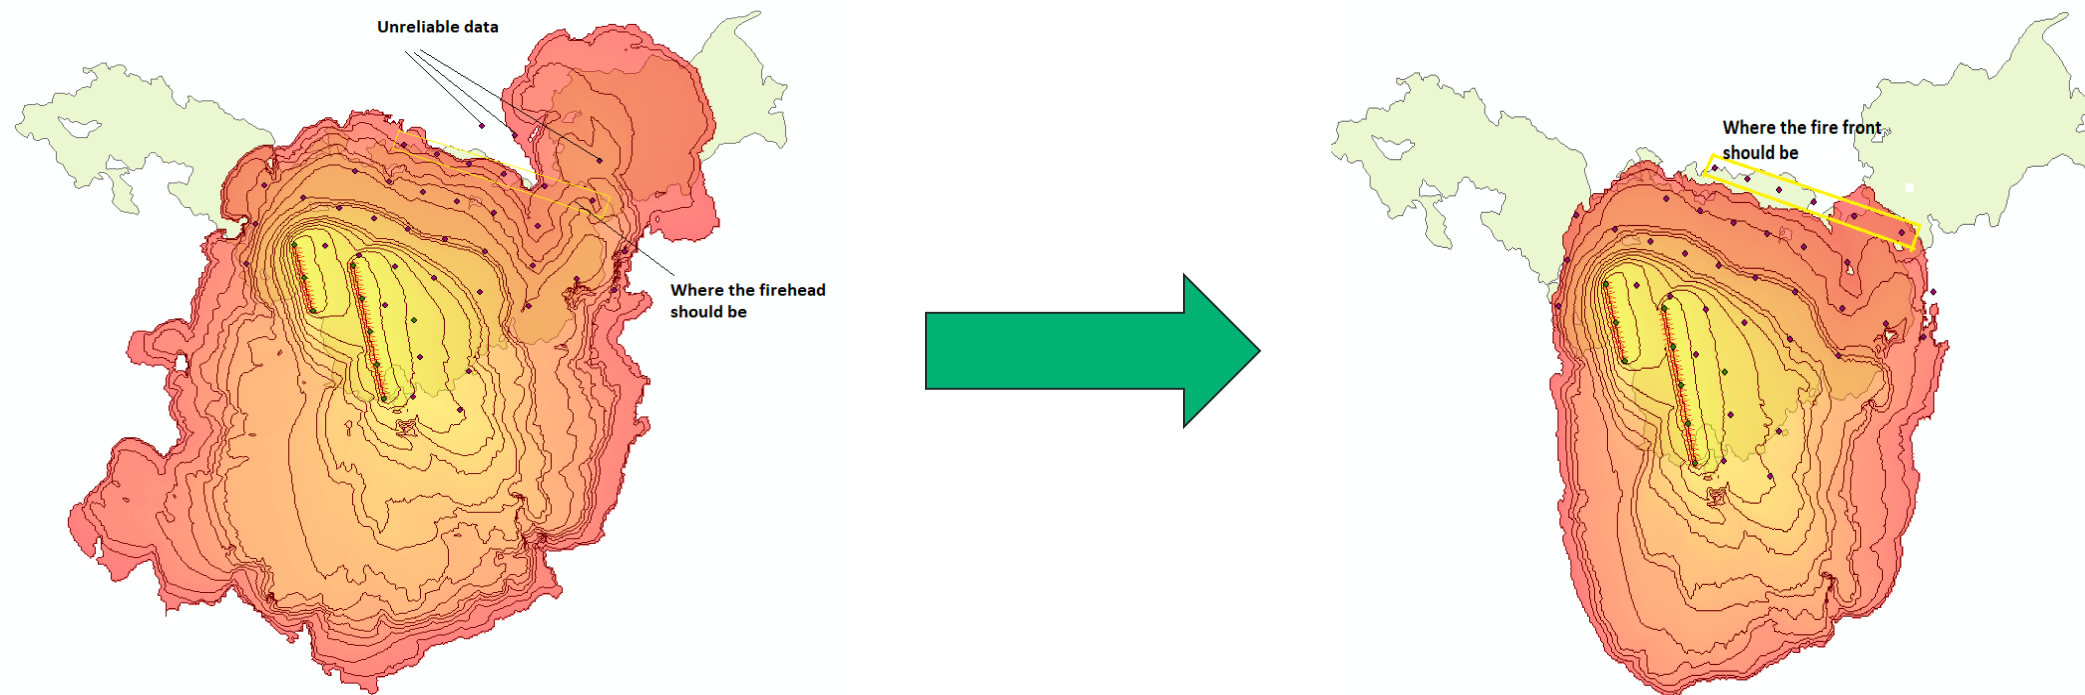

- ◆ Rothermel spread model
- ◆ Nelson's equation for de
- ◆ Inputs:
 - **Fuel Cover: COS20**
 - **Fuel Model: Rotherr**
 - **Digital Elevation M**
 - **Weather** (Instituto Portugu
 - **Satellite Hotspots** (F

Results

Conclusion

- ◆ **Primary Goal:**
 - Improve the Accuracy of Wildfire Simulations
- ◆ **Improvements to Simulation:**
 - A cost-effective, near-real-time approach
- ◆ **Final Results:**
 - MAPE from an average of 71.43% decreased to 13.99% over 5 case studies
- ◆ **Limitations:**
 - 1-3 hour data availability delay.
 - Accuracy of satellite data affected by cloud cover or hot smoke plumes.
 - ROS adjustments are only done on burned fuels.

Thank you for your attention.
